Overview of Synthes TFNA System

The Synthes Trochanteric Femoral Nail Advanced (TFNA) system is designed for the fixation of proximal femoral fractures, including intertrochanteric and subtrochanteric fractures. This intramedullary nail system offers enhanced biomechanical properties to support fracture stabilization while minimizing soft tissue disruption. The TFNA implant combines a slim profile with a helical blade or lag screw option to provide controlled fracture compression and rotational stability.

Design Features

The TFNA system incorporates several innovative design features that contribute to its effectiveness. The nail is made from titanium alloy, ensuring strength and biocompatibility. Its slim diameter allows for less invasive insertion, reducing surgical trauma. The proximal fixation options include a helical blade or lag screw, each providing specific benefits in terms of purchase in the femoral head and load distribution. Distal locking screws secure the implant within the femoral shaft, preventing rotational and axial movement.

Indications and Applications

The Synthes TFNA system is indicated primarily for fixation of unstable proximal femoral fractures in adults. Common applications include:

- Intertrochanteric femoral fractures
- Subtrochanteric femoral fractures
- Reverse obliquity fractures
- Pathologic fractures of the proximal femur

Its design accommodates various fracture patterns and facilitates early mobilization due to its mechanical stability.

Preoperative Planning and Patient Selection

Effective preoperative planning is essential for successful outcomes with the Synthes TFNA technique. Proper patient selection, imaging evaluation, and implant sizing are critical components to consider before surgery.

Patient Assessment

Comprehensive patient evaluation includes assessment of medical history, fracture classification, bone quality, and functional status. Patients with unstable proximal femoral fractures who are medically fit for surgery are ideal candidates. Comorbidities such as osteoporosis or metabolic bone disease should be addressed to optimize healing potential.

Imaging and Fracture Evaluation

Preoperative imaging typically involves standard anteroposterior and lateral radiographs of the affected femur. Computed tomography (CT) scans may be utilized for complex fracture patterns or to assess comminution. Fracture classification systems, such as the AO/OTA classification, assist in surgical planning and implant selection.

Implant Selection and Sizing

Choosing the appropriate nail length, diameter, and proximal fixation type is imperative. Implant sizing is guided by the patient's femoral anatomy and fracture location. The nail length should extend sufficiently distal to provide stability but avoid impingement. The diameter must accommodate the medullary canal without excessive reaming. Surgeons must decide between a helical blade or lag screw based on bone quality and fracture characteristics.

Surgical Technique for Synthes TFNA Implantation

The surgical procedure for Synthes TFNA implantation involves a series of precise steps designed to achieve stable fixation with minimal soft tissue disruption. Familiarity with instrumentation and fluoroscopic guidance is essential throughout the operation.

Patient Positioning and Setup

The patient is positioned supine on a fracture table with the affected leg appropriately draped and accessible for imaging. Traction is applied to achieve fracture reduction under fluoroscopic control. Proper positioning facilitates nail insertion and distal locking screw placement.

Fracture Reduction

Closed reduction is attempted initially using traction and manipulation under fluoroscopy. Achieving anatomic or near-anatomic alignment is critical for optimal implant function. If closed reduction fails, limited open reduction may be necessary.

Entry Point and Nail Insertion

The entry point for the TFNA nail is located at the tip of the greater trochanter. After incision and soft tissue dissection, a guidewire is inserted into the femoral canal under fluoroscopic guidance. Sequential reaming prepares the canal to accommodate the nail diameter. The TFNA nail is then inserted over the guidewire, ensuring correct alignment and depth.

Proximal Fixation Placement

Using targeting instrumentation, the helical blade or lag screw is advanced into the femoral head. Fluoroscopic imaging confirms proper placement, ensuring central or slightly inferior positioning within the femoral head to optimize purchase and minimize cut-out risk. Controlled impaction may be performed to enhance fixation.

Distal Locking

Distal locking screws are inserted through targeting guides to lock the nail within the femoral shaft. Typically, one or two screws are used based on fracture stability. Proper screw length and placement are verified with fluoroscopy to prevent cortical breach or neurovascular injury.

Wound Closure

After confirming implant positioning and fracture stability, the surgical site is irrigated and closed in layers. Attention is given to soft tissue

preservation to promote healing and reduce infection risk.

Postoperative Management and Rehabilitation

Postoperative care following Synthes TFNA implantation focuses on pain control, early mobilization, and monitoring for complications. A multidisciplinary approach enhances recovery and functional outcomes.

Pain Management and Monitoring

Effective analgesia protocols are implemented to facilitate patient comfort and participation in rehabilitation. Regular monitoring of vital signs, wound status, and neurovascular function is essential in the immediate postoperative period.

Mobilization and Weight Bearing

Early mobilization is encouraged to reduce complications such as deep vein thrombosis and muscle atrophy. Weight-bearing status depends on fracture stability and surgeon discretion but often progresses from partial to full weight bearing over several weeks.

Physical Therapy and Follow-up

Physical therapy programs are tailored to improve range of motion, muscle strength, and gait training. Scheduled follow-up visits include radiographic evaluation to assess fracture healing and implant integrity. Adjustments to rehabilitation protocols are made based on patient progress.

Complications and Troubleshooting

Understanding potential complications associated with the Synthes TFNA technique is crucial for prompt identification and management. Awareness of common issues allows for effective troubleshooting and improved patient safety.

Mechanical Complications

Mechanical failures such as implant cut-out, nail breakage, or distal screw loosening may occur. These are often related to poor bone quality, improper implant placement, or inadequate fracture reduction. Preventative measures include meticulous surgical technique and appropriate implant selection.

Infection and Wound Healing

Postoperative infection remains a significant concern. Strict aseptic technique, perioperative antibiotics, and wound care protocols are vital to minimize infection risk. Signs of infection require immediate evaluation and

intervention.

Neurovascular Injury

Careful surgical approach and fluoroscopic guidance help prevent injury to surrounding neurovascular structures. Any postoperative neurologic deficits necessitate prompt assessment and possible surgical revision.

Nonunion and Malunion

Delayed or nonunion can result from inadequate stabilization or patient factors such as smoking or systemic disease. Malalignment may lead to altered biomechanics and functional impairment. Early detection through follow-up imaging allows for timely corrective measures.

1. Ensure precise fracture reduction before implant insertion.
2. Use appropriate implant size and type based on patient anatomy.
3. Employ fluoroscopic guidance continuously throughout the procedure.
4. Monitor for signs of complications during postoperative follow-up.
5. Implement individualized rehabilitation protocols to optimize recovery.
